**Exercise 0.1.** For any language  $L$ , let  $\text{NOREPEATB}(L)$  be the language of strings in  $L$ , but with any  $b$ 's that are immediately preceded by another  $b$  removed. So, for example, if  $\text{babbaaababbb} \in L$ , then  $\text{babaaabab} \in \text{NOREPEATB}(L)$ . Show that if  $L$  is regular, then so is  $\text{NOREPEATB}(L)$ .

Solution:

We want to construct a machine that accepts strings  $s$  without consecutive  $b$ 's such that some number of  $b$ 's can be added after any  $b$  in  $s$  to yield a string in  $L$ . The intuition is to modify a DFA for  $L$  so that its states track the previous character read. If the previous character read was an  $a$ , then it should act much like the DFA for  $L$ . If the previous character read was a  $b$ , then the machine should be able to follow any number of  $\epsilon$  transitions which would simulate what would happen if the DFA for  $L$  read that number of  $b$ 's instead of just one.

Specifically, if  $M = (Q, \Sigma, \delta, q_0, F)$  is the original DFA, let  $M' = (Q', \Sigma, \delta', q_0, F')$  be the NFA that will recognize  $\text{NOREPEATB}(L)$ . We define  $Q'$  as follows: for each  $q_i \in Q$ , let there be a corresponding  $q_i, q'_i \in Q'$ , i.e.,  $Q'$  contains every state in  $Q$  plus a corresponding "prime" state. We will use this notation throughout the proof. Define  $\delta'$  as follows: suppose  $\delta(q_i, a) = q_j$  and  $\delta(q_i, b) = q_k$ . Then

$$\begin{aligned}\delta'(q_i, a) &= \{q_j\} \\ \delta'(q_i, b) &= \{q'_k\} \\ \delta'(q'_i, a) &= \{q_j\} \\ \delta'(q'_i, \epsilon) &= \{q'_k\} \\ \delta'(q'_i, b) &= \emptyset\end{aligned}$$

To summarize,  $M'$  behaves identically to  $M$  when it reads  $a$ : if it is in a prime or a non-prime state, it transitions to the non-prime state that corresponds to the state  $M$  would transition to. When  $M'$  reads  $b$ , its behavior depends on the previous input. If it is in a non-prime state, it transitions to the prime state that corresponds to the state  $M$  would transition to. If it is in a prime state, it enters into a null state on reading  $b$ . Finally, for every  $b$  transition in  $M$  from  $q_i$  to  $q_j$ , there is a corresponding  $\epsilon$  transition in  $M'$  from  $q'_i$  to  $q'_j$ . Finally, for all  $q_i \in F$ , we say let the corresponding states  $q_i, q'_i \in F'$ .

Now, suppose we have a string  $w \in L$ . If  $w$  contains no  $b$ 's or no repeat  $b$ 's, then  $\text{NOREPEATB}(w)$ , which we define to be  $w$  with all repeat  $b$ 's removed, has no  $b$ 's and  $M'$  will behave identically to  $M$  and hence will accept  $\text{NOREPEATB}(l)$ . So, suppose  $w$  has at least one string of one or more repeated  $b$ 's. Then  $M'$  will read  $\text{NOREPEATB}(w)$  until it hits the first  $b$ , at which time it will enter a prime state. It will then undergo  $\epsilon$  transitions for each prime state corresponding to  $M$ 's original behavior on  $w$  on reading the repeated  $b$ 's. Thus,  $M'$ 's behavior on  $\text{NOREPEATB}(w)$  will mimic that of  $M$  on  $w$ , so  $M'$  will accept.

Finally, suppose we have some  $w \notin \text{NOREPEATB}(L)$ . Then we cannot repeat  $b$ 's in  $w$  to achieve a string in  $L$ . Thus, there can be no computation path in  $M'$  that leads to an accept state on reading  $w$ , since the only difference between  $M$  and  $M'$  is that  $M'$  allows  $\epsilon$  transitions in place of transitions in the case of a repeated  $b$  that correspond exactly to  $M$ 's behavior.

Thus  $M'$  accept  $\text{NOREPEATB}(L)$  and only this language, so that  $\text{NOREPEATB}(L)$  is regular.
